

Package ‘qryflow’

February 6, 2026

Title Execute Multi-Step 'SQL' Workflows

Version 0.2.0

Description Execute multi-step 'SQL' workflows by leveraging specially formatted comments to define and control execution. This enables users to mix queries, commands, and metadata within a single script. Results are returned as named objects for use in downstream workflows.

collapse_sql_lines	<i>Collapse SQL lines into single character</i>
--------------------	---

Description

A thin wrapper around paste0(x, collapse = '\\n') to standardize the way qryflow collapses SQL lines.

Usage

```
collapse_sql_lines(x)
```

Arguments

x character vector of SQL lines

Value

a character vector of length 1

Examples

```
path <- example_sql_path()

lines <- read_sql_lines(path)

sql <- collapse_sql_lines(lines)
```

example_db_connect	Create an example in-memory database
--------------------	--------------------------------------

Description

This function creates a connection to an in-memory SQLite database, with the option to add a table to the database. This function is intended to facilitate examples, vignettes, and package tests.

Usage

```
example_db_connect(df = NULL)
```

Arguments

df Optional data.frame to add to the database.

Value

connection from [DBI::dbConnect\(\)](#)

Examples

```
con <- example_db_connect(mtcars)

x <- DBI::dbGetQuery(con, "SELECT * FROM mtcars;")

head(x)

DBI::dbDisconnect(con)
```

example_sql_path	Get path to qryflow example SQL scripts
------------------	---

Description

qryflow provides example SQL scripts in its inst/sql directory. Use this function to retrieve the path to an example script. This function is intended to facilitate examples, vignettes, and package tests.

Usage

```
example_sql_path(path = "mtcars.sql")
```

Arguments

path filename of the example script.

Value

path to example SQL script

Examples

```
path <- example_sql_path("mtcars.sql")
file.exists(path)
```

extract_all_tags	<i>Extract tagged metadata from a SQL chunk</i>
------------------	---

Description

extract_all_tags() scans SQL for specially formatted comment tags (e.g., -- @tag: value) and returns them as a named list. This is exported with the intent to be useful for users extending qryflow. It's typically used against a single SQL chunk, such as one parsed from a .sql file.

Additional helpers like extract_tag(), extract_name(), and extract_type() provide convenient access to specific tag values. subset_tags() lets you filter or exclude tags by name.

Usage

```
extract_all_tags(text, tag_pattern = "^\\s*--\\s*@([^:]+):\\s*(.*)$")
extract_tag(text, tag)
extract_name(text)
extract_type(text)
subset_tags(tags, keep, negate = FALSE)
```

Arguments

text	A character vector of SQL lines or a file path to a SQL script.
tag_pattern	A regular expression for extracting tags. Defaults to lines in the form -- @tag: value.
tag	A character string naming the tag to extract (used in extract_tag()).
tags	A named list of tags, typically from extract_all_tags(). Used in subset_tags().
keep	A character vector of tag names to keep or exclude in subset_tags().
negate	Logical; if TRUE, subset_tags() returns all tags except those listed in keep.

Details

The formal type of a qryflow SQL chunk is determined by `extract_type()` using a prioritized approach:

1. If the chunk includes an explicit `-- @type:` tag, its value is used directly as the chunk type.
2. If the `@type:` tag is absent, qryflow searches for other tags (e.g., `@query:`, `@exec:`) that correspond to registered chunk types through `ls_qryflow_types()`. The first matching tag found defines the chunk type.
3. If neither an explicit `@type:` tag nor any recognized tag is present, the chunk type falls back to the default type returned by `qryflow_default_type()`.

Value

- `extract_all_tags()`: A named list of all tags found in the SQL chunk.
- `extract_tag()`, `extract_name()`, `extract_type()`: A single tag value (character or NULL).
- `subset_tags()`: A filtered named list of tags or NULL if none remain.

See Also

`qryflow_parse()`, `ls_qryflow_types()`, `qryflow_default_type()`

Examples

```
filepath <- example_sql_path('mtcars.sql')
parsed <- qryflow_parse(filepath)

chunk <- parsed$chunks[[1]]
tags <- extract_all_tags(chunk$sql)

extract_name(chunk$sql)
extract_type(chunk$sql)
subset_tags(tags, keep = c("query"))
```

is_tag_line

Detect the presence of a properly structured tagline

Description

Checks whether a specially structured comment line is formatted in the way that qryflow expects.

Usage

```
is_tag_line(line)
```

Arguments

`line` A character vector to check. It is a vectorized function.

Details

Tag lines should look like this: `-- @key: value`

- Begins with an inline comment (`--`)
- An `@` precedes a tag type (e.g., `type`, `name`, `query`, `exec`) and is followed by a colon (`:`)
- A value is provided

Value

Logical. Indicating whether each line matches tag specification.

Examples

```
a <- "-- @query: df_mtcars"
b <- "-- @exec: prep_tbl"
c <- "-- @type: query"

lines <- c(a, b, c)

is_tag_line(lines)
```

ls_qryflow_handlers	<i>List currently registered chunk types</i>
---------------------	--

Description

Helper function to access the names of the currently registered chunk types. Functions available for accessing just the parsers or just the handlers.

Usage

```
ls_qryflow_handlers()

ls_qryflow_parsers()

ls_qryflow_types()
```

Details

`ls_qryflow_types` is implemented to return the union of the results of `ls_qryflow_parsers` and `ls_qryflow_handlers`. It's expected that both a parser and a handler exist for each type. If this assumption is violated, the `ls_qryflow_types` may suggest otherwise.

Value

Character vector of registered chunk types

Examples

```
ls_qryflow_types()
```

new_qryflow_chunk	Create an instance of the qryflow_chunk class
-------------------	---

Description

Create an instance of the qryflow_chunk class

Usage

```
new_qryflow_chunk(  
  type = character(),  
  name = character(),  
  sql = character(),  
  tags = NULL,  
  results = NULL  
)
```

Arguments

type	Character indicating the type of chunk (e.g., "query", "exec")
name	Name of the chunk
sql	SQL statement associated with chunk
tags	Optional, additional tags included in chunk
results	Optional, filled in after chunk execution

Details

Exported for users intending to extend qryflow. Subsequent processes rely on the structure of a qryflow_chunk.

Value

An list-like object of class qryflow_chunk

Examples

```
chunk <- new_qryflow_chunk("query", "df_name", "SELECT * FROM mtcars;")
```

qryflow

Run a multi-step SQL workflow and return query results

Description

`qryflow()` is the main entry point to the `qryflow` package. It executes a SQL workflow defined in a tagged `.sql` script or character string and returns query results as R objects.

The SQL script can contain multiple steps tagged with `@query` or `@exec`. Query results are captured and returned as a named list, where names correspond to the `@query` tags.

Usage

```
qryflow(con, sql, ..., simplify = TRUE)
```

Arguments

<code>con</code>	A database connection from <code>DBI::dbConnect()</code>
<code>sql</code>	A file path to a <code>.sql</code> workflow or a character string containing SQL code.
<code>...</code>	Additional arguments passed to <code>qryflow_run()</code> or <code>qryflow_results()</code> .
<code>simplify</code>	Logical; if <code>TRUE</code> (default), a list of length 1 is simplified to the single result object.

Details

This is a wrapper around the combination of `qryflow_run()`, which always provides a list of results and metadata, and `qryflow_results()`, which filters the output of `qryflow_run()` to only include the results of the SQL.

Value

A named list of query results, or a single result if `simplify = TRUE` and only one chunk exists.

See Also

`qryflow_run()`, `qryflow_results()`

Examples

```
con <- example_db_connect(mtcars)

filepath <- example_sql_path("mtcars.sql")

results <- qryflow(con, filepath)

head(results$df_mtcars)

DBI::dbDisconnect(con)
```

qryflow_default_type *Access the default qryflow chunk type*

Description

Retrieves the value from the option `qryflow.default.type`, if set. Otherwise returns "query", which is the officially supported default type. If any value is supplied to the function, it returns that value.

Usage

```
qryflow_default_type(type = getOption("qryflow.default.type", "query"))
```

Arguments

type Optional. The type you want to return.

Value

Character. If set, result from `qryflow.default.type` option, otherwise "query" or value passed to `type`

Examples

```
x <- getOption("qryflow.default.type", "query")

y <- qryflow_default_type()

identical(x, y)
```

qryflow_execute *Execute a parsed qryflow SQL workflow*

Description

`qryflow_execute()` takes a parsed workflow object (as returned by [qryflow_parse\(\)](#)), executes each chunk (e.g., @query, @exec), and collects the results and timing metadata.

This function is used internally by [qryflow_run\(\)](#), but can be called directly in concert with [qryflow_parse\(\)](#) if you want to manually control parsing and execution.

Usage

```
qryflow_execute(con, x, ..., source = NULL)
```

Arguments

con	A database connection from <code>DBI::dbConnect()</code>
x	A parsed qryflow workflow object, typically created by <code>qryflow_parse()</code>
...	Reserved for future use.
source	Optional; a character string indicating the source SQL to include in metadata.

Value

An object of class `qryflow_result`, containing executed chunks with results and a meta field that includes timing and source information.

See Also

`qryflow_run()`, `qryflow_parse()`

Examples

```
con <- example_db_connect(mtcars)

filepath <- example_sql_path("mtcars.sql")

parsed <- qryflow_parse(filepath)

executed <- qryflow_execute(con, parsed, source = filepath)

DBI::dbDisconnect(con)
```

`qryflow_handler_exists`

Check existence of a given handler in the registry

Description

Checks whether the specified handler exists in the handler registry environment.

Usage

```
qryflow_handler_exists(type)
```

Arguments

type	chunk type to check (e.g., "query", "exec")
------	---

Value

Logical. Does type exist in the handler registry?

See Also

[qryflow_parser_exists\(\)](#) for the parser equivalent.

Examples

```
qryflow_handler_exists("query")
```

qryflow_parse	<i>Parse a SQL workflow into tagged chunks</i>
---------------	--

Description

`qryflow_parse()` reads a SQL workflow file or character vector and parses it into discrete tagged chunks based on `@query`, `@exec`, and other custom markers.

Usage

```
qryflow_parse(sql)
```

Arguments

sql	A file path to a SQL workflow file, or a character vector containing SQL lines.
-----	---

Details

This function is used internally by [qryflow_run\(\)](#), but can also be used directly to preprocess or inspect the structure of a SQL workflow.

Value

An object of class `qryflow_workflow`, which is a structured list of SQL chunks and metadata.

See Also

[qryflow\(\)](#), [qryflow_run\(\)](#), [qryflow_execute\(\)](#)

Examples

```
filepath <- example_sql_path("mtcars.sql")  
  
parsed <- qryflow_parse(filepath)
```

<code>qryflow_parser_exists</code>	<i>Check existence of a given parser in the registry</i>
------------------------------------	--

Description

Checks whether the specified parser exists in the parser registry environment.

Usage

```
qryflow_parser_exists(type)
```

Arguments

<code>type</code>	chunk type to check (e.g., "query", "exec")
-------------------	---

Value

Logical. Does type exist in the parser registry?

See Also

[qryflow_handler_exists\(\)](#) for the handler equivalent.

Examples

```
qryflow_parser_exists("query")
```

<code>qryflow_results</code>	<i>Extract results from a qryflow_workflow object</i>
------------------------------	---

Description

`qryflow_results()` retrieves the query results from a list returned by [qryflow_run\(\)](#), typically one that includes parsed and executed SQL chunks.

Usage

```
qryflow_results(x, ..., simplify = FALSE)
```

Arguments

<code>x</code>	Results from qryflow_run() , usually containing a mixture of <code>qryflow_chunk</code> objects.
<code>...</code>	Reserved for future use.
<code>simplify</code>	Logical; if TRUE, simplifies the result to a single object if only one query chunk is present. Defaults to FALSE.

Value

A named list of query results, or a single result object if `simplify = TRUE` and only one result is present.

See Also

[qryflow\(\)](#), [qryflow_run\(\)](#)

Examples

```
con <- example_db_connect(mtcars)

filepath <- example_sql_path("mtcars.sql")

obj <- qryflow_run(con, filepath)

results <- qryflow_results(obj)

DBI::dbDisconnect(con)
```

qryflow_run	<i>Parse and execute a tagged SQL workflow</i>
-------------	--

Description

`qryflow_run()` reads a SQL workflow from a file path or character string, parses it into tagged statements, and executes those statements against a database connection.

This function is typically used internally by [qryflow\(\)](#), but can also be called directly for more control over workflow execution.

Usage

```
qryflow_run(con, sql, ...)
```

Arguments

<code>con</code>	A database connection from DBI::dbConnect()
<code>sql</code>	A character string representing either the path to a .sql file or raw SQL content.
<code>...</code>	Additional arguments passed to qryflow_execute() .

Value

A list representing the evaluated workflow, containing query results, execution metadata, or both, depending on the contents of the SQL script.

See Also

[qryflow\(\)](#), [qryflow_results\(\)](#), [qryflow_execute\(\)](#), [qryflow_parse\(\)](#)

Examples

```

con <- example_db_connect(mtcars)

filepath <- example_sql_path("mtcars.sql")

obj <- qryflow_run(con, filepath)

obj$df_mtcars$sql
obj$df_mtcars$results

results <- qryflow_results(obj)

head(results$df_mtcars$results)

DBI::dbDisconnect(con)

```

read_sql_lines	<i>Standardizes lines read from string, character vector, or file</i>
----------------	---

Description

This is a generic function to ensure lines read from a file, a single character vector, or already parsed lines return the same format. This helps avoid re-reading entire texts by enabling already read lines to pass easily.

This is useful for folks who may want to extend qryflow.

Usage

```
read_sql_lines(x)
```

Arguments

`x` a filepath or character vector containing SQL

Value

A `qryflow_sql` object (inherits from character) with a length equal to the number of lines read

Examples

```

# From a file #####
path <- example_sql_path()
read_sql_lines(path)

# From a single string #####
sql <- "SELECT *
FROM mtcars;"
read_sql_lines(sql)

```

```
# From a character #####
lines <- c("SELECT *", "FROM mtcars;")
read_sql_lines(lines)
```

register_qryflow_type *Register custom chunk types*

Description

Use these functions to register the parsers and handlers associated with custom types. `register_qryflow_type` is a wrapper around both `register_qryflow_parser` and `register_qryflow_handler`.

Usage

```
register_qryflow_type(type, parser, handler, overwrite = FALSE)

register_qryflow_parser(type, parser, overwrite = FALSE)

register_qryflow_handler(type, handler, overwrite = FALSE)
```

Arguments

<code>type</code>	Character indicating the chunk type (e.g., "exec", "query")
<code>parser</code>	A function to parse the SQL associated with the type. Must accept arguments "x" and "..." and return a <code>qryflow_chunk</code> object.
<code>handler</code>	A function to execute the SQL associated with the type. Must accept arguments "chunk", "con", and "...".
<code>overwrite</code>	Logical. Overwrite existing parser and handler, if exists?

Details

To avoid manually registering your custom type each session, consider adding the registration code to your `.Rprofile` or creating a package that leverages `.onLoad()`

Value

Logical. Indicating whether types were successfully registered.

Examples

```
# Create custom parser #####
custom_parser <- function(x, ...){
  # Custom parsing code will go here

  # new_qryflow_chunk(type = "custom", name = name, sql = sql_txt, tags = tags)
}

# Create custom handler #####
```

```

custom_handler <- function(con, chunk, ...){
  # Custom execution code will go here...
  # return(result)
}

# Register Separately #####
register_qryflow_parser("custom", custom_parser, overwrite = TRUE)

register_qryflow_handler("custom", custom_handler, overwrite = TRUE)

# Register Simultaneously #####
register_qryflow_type("query-send", custom_parser, custom_handler, overwrite = TRUE)

```

validate_qryflow_handler

Ensure correct handler structure

Description

This function checks that the passed object is a function and contains the arguments "chunk", "con", and "..." - in that order. This is to help ensure users only register valid handlers.

Usage

```
validate_qryflow_handler(handler)
```

Arguments

handler	object to check
---------	-----------------

Value

Logical. Generates an error if the object does not pass all the criteria.

See Also

[validate_qryflow_parser\(\)](#) for the parser equivalent.

Examples

```

custom_func <- function(con, chunk, ...){

  # Parsing Code Goes Here

}

validate_qryflow_handler(custom_func)

```

`validate_qryflow_parser`*Ensure correct parser structure*

Description

This function checks that the passed object is a function and contains the arguments "x" and "..." - in that order. This is to help ensure users only register valid parsers.

Usage

```
validate_qryflow_parser(parser)
```

Arguments

parser	object to check
--------	-----------------

Value

Logical. Generates an error if the object does not pass all the criteria.

See Also

[validate_qryflow_handler\(\)](#) for the handler equivalent.

Examples

```
custom_func <- function(x, ...){  
  # Parsing Code Goes Here  
}  
validate_qryflow_parser(custom_func)
```
